Introduction

Dynamic system simulation: map from inputs to outputs

The aim of numerical simulation

Aim of numerical simulation:

Compute $x(t), t \in [t_0, t_{end}]$ which approximately satisfies

$$\dot{x}(t) = f(t, x(t), u(t), p), \quad t \in [t_0, t_{ ext{end}}], \ x(t_0) = x_0,$$

and z(t) in case of index-1 DAE

$$\dot{x}(t) = f(t, x(t), z(t), u(t), p),$$

 $0 = g(t, x(t), z(t), u(t), p), \quad t \in [t_0, t_{end}],$
 $x(t_0) = x_0$

NOTE: interested in values at discrete times $t_i \in [t_0, t_{end}]$, especially $t = t_{end}$. Denote approximations by $\hat{x}(t_i)$

Local and global error

Let us define the exact trajectory $x(t), t \in [t_0, t_{end}]$ and a set of discrete time steps t_0, t_1, \ldots

Local and global error

Let us define the exact trajectory $x(t), t \in [t_0, t_{end}]$ and a set of discrete time steps t_0, t_1, \ldots

Local error:

$$e(t_i) = x(t_i) - \hat{x}(t_i; t_{i-1}, x(t_{i-1}))$$

Local and global error

Let us define the exact trajectory $x(t), t \in [t_0, t_{end}]$ and a set of discrete time steps t_0, t_1, \ldots

Local error:

$$e(t_i) = x(t_i) - \hat{x}(t_i; t_{i-1}, x(t_{i-1}))$$

Global error or "transported error":

$$E(t_i) = x(t_i) - \hat{x}(t_i; t_0, x_0)$$

・ロン ・回 とくほど くほどう ほう

4/38

Let us define the stepsize *h* such that $t_{i+1} = t_i + h$

Let us define the stepsize *h* such that $t_{i+1} = t_i + h$

convergence: A method is convergent when its values converge to the exact solution for $h \rightarrow 0$.

Let us define the stepsize *h* such that $t_{i+1} = t_i + h$

convergence: A method is convergent when its values converge to the exact solution for $h \rightarrow 0$. **consistency order**: The method has order p if the local error

$$\lim_{h\to 0} e(t_i) = O(h^{p+1})$$

NOTE: consistency when p > 0 (necessary for convergence)

Let us define the stepsize *h* such that $t_{i+1} = t_i + h$

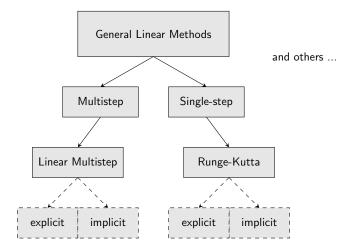

convergence: A method is convergent when its values converge to the exact solution for $h \rightarrow 0$. **consistency order**: The method has order p if the local error

$$\lim_{h\to 0} e(t_i) = O(h^{p+1})$$

NOTE: consistency when p > 0 (necessary for convergence)

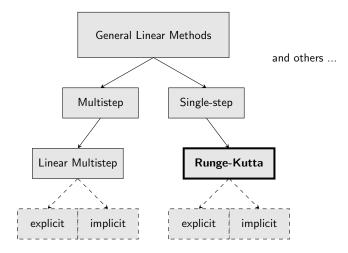

stability: 'damping' of errors, see stiffness. Also necessary for convergence.

Classes of numerical methods:

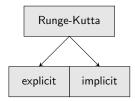

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ = 臣 = のへで

Classes of numerical methods:

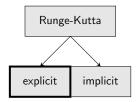

Runge-Kutta methods:

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ● ● ●

Runge-Kutta methods:

The simplest ERK method is explicit Euler

The simplest ERK method is explicit Euler

$$x_n = x_{n-1} + h f_{n-1}$$

which is consistent of order one. (abbreviate $f_n := f(t_n, x_n)$)

The simplest ERK method is explicit Euler

$$x_n = x_{n-1} + h f_{n-1}$$

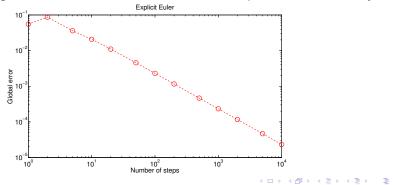

which is consistent of order one. (abbreviate $f_n := f(t_n, x_n)$) BUT: it is typically not a practical method... Why?

The simplest ERK method is explicit Euler

$$x_n = x_{n-1} + h f_{n-1}$$

which is consistent of order one. (abbreviate $f_n := f(t_n, x_n)$)

BUT: it is typically not a practical method... Why? Higher order methods need much fewer steps for same accuracy!

8 / 38

The most popular is the following 4th order method

9/38

The most popular is the following 4th order method

$$k_{1} = f(t_{n-1}, x_{n-1})$$

$$k_{2} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{1})$$

$$k_{3} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{2})$$

$$k_{4} = f(t_{n-1} + h, x_{n-1} + h k_{3})$$

$$x_{n} = x_{n-1} + \frac{h}{6}(k_{1} + 2k_{2} + 2k_{3} + k_{4})$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

The most popular is the following 4th order method

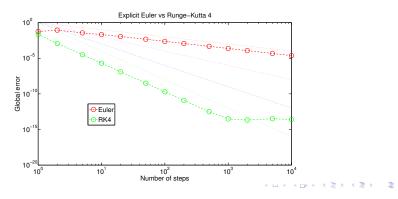

$$k_{1} = f(t_{n-1}, x_{n-1})$$

$$k_{2} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{1})$$

$$k_{3} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{2})$$

$$k_{4} = f(t_{n-1} + h, x_{n-1} + hk_{3})$$

$$x_{n} = x_{n-1} + \frac{h}{6}(k_{1} + 2k_{2} + 2k_{3} + k_{4})$$

The RK4 method

$$k_{1} = f(t_{n-1}, x_{n-1})$$

$$k_{2} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{1})$$

$$k_{3} = f(t_{n-1} + \frac{h}{2}, x_{n-1} + \frac{h}{2}k_{2})$$

$$k_{4} = f(t_{n-1} + h, x_{n-1} + h k_{3})$$

$$x_{n} = x_{n-1} + \frac{h}{6}(k_{1} + 2k_{2} + 2k_{3} + k_{4})$$

4 ロ ト 4 部 ト 4 差 ト 4 差 ト 差 の Q で 10 / 38

So a general s-stage ERK method

$$k_{1} = f(t_{n-1}, x_{n-1})$$

$$k_{2} = f(t_{n-1} + c_{2} h, x_{n-1} + a_{21} h k_{1})$$

$$k_{3} = f(t_{n-1} + c_{3} h, x_{n-1} + a_{31} h k_{1} + a_{32} h k_{2})$$

$$\vdots$$

$$k_{s} = f(t_{n-1} + c_{s} h, x_{n-1} + a_{s1} h k_{1} + a_{s2} h k_{2} + \dots + a_{s,s-1} h k_{s-1})$$

$$x_{n} = x_{n-1} + h \sum_{i=1}^{s} b_{i} k_{i}$$

So a general s-stage ERK method

$$\begin{split} k_1 &= f(t_{n-1}, x_{n-1}) \\ k_2 &= f(t_{n-1} + c_2 h, x_{n-1} + a_{21} h k_1) \\ k_3 &= f(t_{n-1} + c_3 h, x_{n-1} + a_{31} h k_1 + a_{32} h k_2) \\ \vdots \\ k_s &= f(t_{n-1} + c_s h, x_{n-1} + a_{s1} h k_1 + a_{s2} h k_2 + \ldots + a_{s,s-1} h k_{s-1}) \\ k_s &= f(t_{n-1} + c_s h, x_{n-1} + a_{s1} h k_1 + a_{s2} h k_2 + \ldots + a_{s,s-1} h k_{s-1}) \\ x_n &= x_{n-1} + h \sum_{i=1}^{s} b_i k_i \end{split}$$

So a general s-stage ERK method

$$\begin{aligned} &k_1 = f(t_{n-1}, x_{n-1}) \\ &k_2 = f(t_{n-1} + c_2 h, x_{n-1} + a_{21} h k_1) \\ &k_3 = f(t_{n-1} + c_3 h, x_{n-1} + a_{31} h k_1 + a_{32} h k_2) \\ &\vdots \\ &k_s = f(t_{n-1} + c_s h, x_{n-1} + a_{s1} h k_1 + a_{s2} h k_2 + \ldots + a_{s,s-1} h k_{s-1}) \\ &k_s = r_{n-1} + h \sum_{i=1}^{s} b_i k_i \end{aligned}$$

NOTE: each Runge-Kutta method is defined by its Butcher table! other examples are e.g. the methods of Runge and Heun, ...

Typically:

no constant step size but suitable error control

Typically:

no constant step size but suitable error control based on a local error estimate:

$$e_i \approx \|x(t_i) - x(t_i; t_{i-1}, x(t_{i-1}))\|$$

Example:

Euler: $x_n = x_{n-1} + h f_{n-1}$

Example:

Euler: $x_n = x_{n-1} + h f_{n-1}$

Let us create a reference solution using 2 steps with h/2:

$$x_{n-1/2} = x_{n-1} + \frac{h}{2} f_{n-1}$$
$$\tilde{x}_n = x_{n-1/2} + \frac{h}{2} f_{n-1/2}$$

Example:

Euler: $x_n = x_{n-1} + h f_{n-1}$

Let us create a reference solution using 2 steps with h/2:

$$x_{n-1/2} = x_{n-1} + \frac{h}{2} f_{n-1}$$
$$\tilde{x}_n = x_{n-1/2} + \frac{h}{2} f_{n-1/2}$$

12/38

 $e_n = \tilde{x}_n - x_n \implies \text{accept/reject}$ and update the step size: $h_n = 0.9 h_{n-1} \sqrt[p+1]{\frac{TOL}{E}}$

Example:

Euler: $x_n = x_{n-1} + h f_{n-1}$

Let us create a reference solution using 2 steps with h/2:

$$x_{n-1/2} = x_{n-1} + \frac{h}{2} f_{n-1}$$
$$\tilde{x}_n = x_{n-1/2} + \frac{h}{2} f_{n-1/2}$$

 $e_n = \tilde{x}_n - x_n \implies \text{accept/reject}$ and update the step size: $h_n = 0.9 h_{n-1} \sqrt[p+1]{\frac{TOL}{E}}$

Embedded methods: Fehlberg (e.g. RKF45), Dormand-Prince, ...

Stiffness

"... stiff equations are equations where certain implicit methods ... perform better, usually tremendously better, than explicit ones."

- (Curtiss & Hirschfelder, 1952)

Stiffness

"... stiff equations are equations where certain implicit methods ... perform better, usually tremendously better, than explicit ones."

- (Curtiss & Hirschfelder, 1952)

"... Around 1960, things became completely different and everyone became aware that the world was full of stiff problems."

- (G. Dahlquist, 1985)

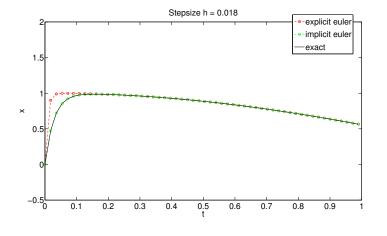

Let us consider the following simple one-dimensional system

$$\dot{x}(t) = -50(x(t) - \cos(t))$$

Stiffness example

Let us consider the following simple one-dimensional system

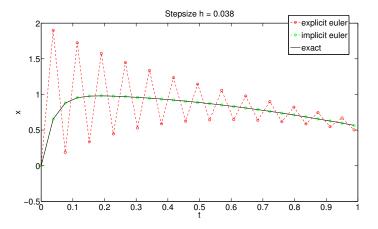

$$\dot{x}(t) = -50(x(t) - \cos(t))$$

Stiffness example

Let us consider the following simple one-dimensional system

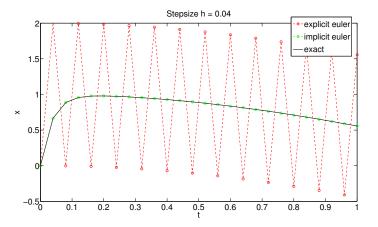

$$\dot{x}(t) = -50(x(t) - \cos(t))$$

Stiffness example

Let us consider the following simple one-dimensional system

$$\dot{x}(t) = -50(x(t) - \cos(t))$$

Explicit vs. Implicit Euler

Explicit Euler:

$$x_n = x_{n-1} + h f(t_{n-1}, x_{n-1})$$

Implicit Euler:

$$x_n = x_{n-1} + hf(t_n, x_n)$$

For given x_{n-1} , implicit method needs root finding solver to find x_n .

Stiffness depends largely on

Stiffness depends largely on

- the eigenvalues $\lambda(t)$ of the Jacobian $\frac{\partial f}{\partial x}$
- but also system dimension, smoothness of the solution, ...

Stiffness depends largely on

- the eigenvalues $\lambda(t)$ of the Jacobian $\frac{\partial f}{\partial x}$
- but also system dimension, smoothness of the solution, ...

\Downarrow

- various mathematical definitions exist
- new concepts needed:
 A-stability, I-stability, A(α)-stability, L-stability, ...

Stiffness depends largely on

Important family of IRK methods:

- distinct c_i's (nonconfluent)
- polynomial q(t) of degree s

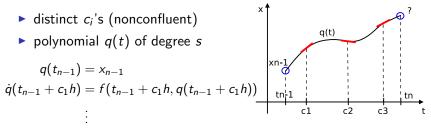

Important family of IRK methods:

continuous approximation

$$\Rightarrow \quad x_n = q(t_{n-1} + h)$$

Important family of IRK methods:

$$\dot{q}(t_{n-1}+c_sh)=f(t_{n-1}+c_sh,q(t_{n-1}+c_sh))$$

continuous approximation

$$\Rightarrow x_n = q(t_{n-1}+h)$$

NOTE: this is very popular in direct optimal control!

How to implement a collocation method?

$$\begin{aligned} q(t_{n-1}) &= x_{n-1} \\ \dot{q}(t_{n-1}+c_1h) &= f(t_{n-1}+c_1h, q(t_{n-1}+c_1h)) \\ &\vdots \\ \dot{q}(t_{n-1}+c_sh) &= f(t_{n-1}+c_sh, q(t_{n-1}+c_sh)) \end{aligned}$$

◆□ ▶ ◆□ ▶ ◆目 ▶ ◆□ ▶ ◆□ ◆ ◆ ●

22 / 38

How to implement a collocation method?

$$\begin{split} q(t_{n-1}) &= x_{n-1} \\ \dot{q}(t_{n-1}+c_1h) &= f(t_{n-1}+c_1h, q(t_{n-1}+c_1h)) \\ & \vdots \\ \dot{q}(t_{n-1}+c_sh) &= f(t_{n-1}+c_sh, q(t_{n-1}+c_sh)) \end{split}$$

This is nothing else than ...

$$k_{1} = f(t_{n-1} + c_{1} h, x_{n-1} + h \sum_{j=1}^{s} a_{1j} k_{j})$$

$$\vdots$$

$$k_{s} = f(t_{n-1} + c_{s} h, x_{n-1} + h \sum_{j=1}^{s} a_{sj} k_{j})$$

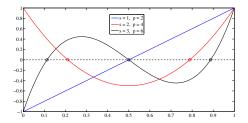

$$x_{n} = x_{n-1} + h \sum_{i=1}^{s} b_{i} k_{i}$$

where the Butcher table is defined by the collocation nodes c_i .

Example: The Gauss methods

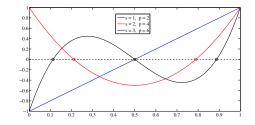

Example: The Gauss methods

- roots of Legendre polynomials
- A-stable
- optimal order (p = 2s)

Example: The Gauss methods

- roots of Legendre polynomials
- A-stable
- optimal order (p = 2s)

$$c_{1} = \frac{1}{2}, \qquad s = 1, \quad p = 2,$$

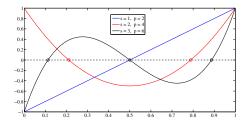

$$c_{1} = \frac{1}{2} - \frac{\sqrt{3}}{6}, c_{2} = \frac{1}{2} + \frac{\sqrt{3}}{6}, \qquad s = 2, \quad p = 4,$$

$$c_{1} = \frac{1}{2} - \frac{\sqrt{15}}{10}, c_{2} = \frac{1}{2}, c_{3} = \frac{1}{2} + \frac{\sqrt{15}}{10}, \quad s = 3, \quad p = 6.$$

 $\begin{array}{l} \Downarrow \quad \text{integrate} \\ X_{k+1} = X_k + h \, F(X_k) \end{array}$

Variational Differential Equations

"differentiate-then-integrate"

Solve additional matrix differential equation

$$\dot{x} = f(x) \qquad \qquad x(0) = x_0, \ x(t_N) = x_N \\ \dot{S} = \frac{\partial f}{\partial x} S \qquad \qquad S(0) = d, \ S(t_N) = \frac{\partial x_N}{\partial x_0} d$$

◆□> ◆圖> ◆臣> ◆臣> ○臣

Variational Differential Equations

"differentiate-then-integrate"

Solve additional matrix differential equation

$$\dot{x} = f(x) \qquad x(0) = x_0, \ x(t_N) = x_N$$

$$\dot{S} = \frac{\partial f}{\partial x} S \qquad S(0) = d, \ S(t_N) = \frac{\partial x_N}{\partial x_0} d$$

Very accurate at reasonable costs, but:

- Have to get expressions for $\frac{\partial f}{\partial x}(\cdot)$.
- Computed sensitivity is not 100 % identical with derivative of (discretized) integrator result Φ(·).
- What about implicit integration schemes?

External Numerical Differentiation (END)

"integrate-then-differentiate"

Finite differences: perturb x_0 and call integrator several times

$$\frac{x(t_N; x_0 + \epsilon e_i) - x(t_N; x_0)}{\epsilon}$$

External Numerical Differentiation (END)

"integrate-then-differentiate"

Finite differences: perturb x_0 and call integrator several times

$$\frac{x(t_N; x_0 + \epsilon e_i) - x(t_N; x_0)}{\epsilon}$$

Very easy to implement, but several problems:

- Relatively expensive with overhead of error control.
- ► How to choose perturbation stepsize? Rule of thumb: $\epsilon = \sqrt{\text{TOL}}$ where TOL is integrator tolerance.
- ► Loss of half the digits of accuracy: if integrator accuracy has value of TOL = 10⁻⁴, derivative has only two valid digits!

External Numerical Differentiation (END)

"integrate-then-differentiate"

Finite differences: perturb x_0 and call integrator several times

$$\frac{x(t_N; x_0 + \epsilon e_i) - x(t_N; x_0)}{\epsilon}$$

Very easy to implement, but several problems:

- Relatively expensive with overhead of error control.
- ► How to choose perturbation stepsize? Rule of thumb: $\epsilon = \sqrt{\text{TOL}}$ where TOL is integrator tolerance.
- ► Loss of half the digits of accuracy: if integrator accuracy has value of $TOL = 10^{-4}$, derivative has only two valid digits!
- Due to adaptivity, each call might have different discretization grids: output x(t_N; x₀) is not differentiable!

Internal Numerical Differentiation (IND)

"integrate-then-differentiate"

Like END, but evaluate simultaneously all perturbed trajectories x_i with frozen discretization grid.

Up to round-off and linearization errors identical with derivative of numerical solution $\Phi(\cdot),$ but:

How to choose perturbation stepsize?

Internal Numerical Differentiation (IND)

"integrate-then-differentiate"

Like END, but evaluate simultaneously all perturbed trajectories x_i with frozen discretization grid.

Up to round-off and linearization errors identical with derivative of numerical solution $\Phi(\cdot),$ but:

• How to choose perturbation stepsize? Rule of thumb: $\epsilon = \sqrt{PREC}$ where PREC is machine precision.

Internal Numerical Differentiation (IND)

"integrate-then-differentiate"

Like END, but evaluate simultaneously all perturbed trajectories x_i with frozen discretization grid.

Up to round-off and linearization errors identical with derivative of numerical solution $\Phi(\cdot),$ but:

• How to choose perturbation stepsize? Rule of thumb: $\epsilon = \sqrt{PREC}$ where PREC is machine precision.

Note: adaptivity of nominal trajectory only, reuse of matrix factorization in implicit methods, so not only more accurate, but also cheaper than END!

Algorithmic Differentiation (AD)

"integrate-then-differentiate"

Use Algorithmic Differentiation (AD) to differentiate each step of the integration scheme.

イロン イロン イヨン イヨン 三日

Algorithmic Differentiation (AD)

"integrate-then-differentiate"

$$\mathbf{x_n} + \mathbf{a_{s-1}} \mathbf{x_{n-1}} + \dots + \mathbf{a_0} \mathbf{x_{n-s}} = h\left(\underline{b_s}\mathbf{f_n} + b_{s-1}f_{n-1} + \dots + b_0f_{n-s}\right)$$

 $\text{explicit } (b_s = 0) \quad \leftrightarrow \quad \text{implicit } (b_s \neq 0) \\$

Three main families:

- Adams-Bashforth (explicit)
- Adams-Moulton (implicit)
- Backward differentiation formulas (BDF)

Simulation methods: software

Simulation for optimization:

▶ ...

► *SUNDIALS*: BDF and Adams in CVODE(S) + BDF in IDA(S)

- SolvIND: BDF in DAESOL-II + RK in RKFSWT
- ACADO Toolkit: BDF and (I)RK methods

High order schemes preferable for smooth problems

- High order schemes preferable for smooth problems
- Explicit methods are good for non-stiff systems

Summary

- High order schemes preferable for smooth problems
- Explicit methods are good for non-stiff systems
- For stiff and/or implicit models, the use of implicit methods (BDF, IRK, ...) is highly recommended
